Experiment 9
Exploration of AI-Enabled Capabilities Embedded in Modern No-Code Applications

Aim
To explore the artificial intelligence (AI) features that are available inside modern no-code and low-code platforms and to understand how they make application development and use easier.

Objectives
- To understand how AI is being added to no-code platforms.
- To identify common AI features such as text analysis, prediction, document scanning and chatbots.
- To try one or two AI features in a no-code platform.
- To discuss the advantages and limitations of AI in no-code applications.

Introduction
Earlier, adding AI to an application needed data scientists and programmers. Today many no-code platforms provide AI as a ready-made feature. The user only has to select the feature and connect it to a field or a form. Examples include Zia in Zoho Creator, Copilot in Microsoft Power Apps and Gemini-based features in Google AppSheet. The exact features and their names may change with new releases, so the latest list should be checked on the platform website.

Common AI Capabilities

AI Capability	What It Does	Example Use
Natural language app building	Creates a basic app or form from a text description typed by the user	Typing "create a leave request app" generates the form fields
Text analysis	Finds sentiment or key words in text	Checking whether customer feedback is positive or negative
Text and image recognition (OCR)	Reads text from images or scanned documents	Reading the amount and date from a bill photo
Prediction	Uses old data to estimate a future value	Predicting whether a sales lead will convert
Chatbot / assistant	Answers questions in natural language	Asking "show leaves taken this month" and getting a report
Smart suggestions	Suggests field types, formulas and workflow steps	Suggesting a dropdown for a Department field

Platform Examples

Platform	AI Features Available (general)
Zoho Creator	Zia assistant, text analysis, OCR, prediction, app building help
Microsoft Power Apps	Copilot to build apps with prompts, AI Builder for forms processing and prediction
Google AppSheet	AI help for app creation, data extraction from images
Airtable	AI fields for summarising, categorising and writing text

Procedure

1. Log in to a no-code platform that offers AI features (for example Zoho Creator trial account).
2. Create a simple "Customer Feedback" form with the fields Name, Product and Comments.
3. Add an AI field or action that checks the sentiment of the Comments field.
4. Submit at least five feedback entries, some positive, some negative and some neutral.
5. Open the report and note the sentiment given by the AI for each entry.
6. Check whether the result matches the meaning of the comment and note any wrong results.

Observations

Comment Entered	Expected Result	AI Result
The product quality is very good	Positive	Positive
Delivery was late and packing was poor	Negative	Negative
I received the item on Monday	Neutral	Neutral
Not bad, but could be cheaper	Neutral / Mixed	Neutral
Great, another delay again	Negative (sarcasm)	May be wrong

The AI results above are sample observations. Results may differ depending on the platform and the version used.

Advantages and Limitations

Advantages	Limitations
Saves time in building apps and processing data	AI may give wrong results, especially for sarcasm or unclear text

Advantages	Limitations
No knowledge of machine learning is needed	Data may be sent to the cloud, so privacy has to be considered
Improves decision making through predictions	Some AI features are available only in paid plans
Reduces manual data entry using OCR	Results should still be checked by a person

Precautions While Using AI Features

- Do not enter personal or confidential data while testing AI features.
- Always read the output of the AI before using it for a decision.
- Check the pricing page, because many AI features are limited in free plans.
- Test the feature with different types of sample data before using it in a real application.

Result

AI features available in no-code platforms were studied and a sentiment analysis feature was tried on a feedback form. The AI gave correct results for most simple comments but was less reliable for mixed or sarcastic comments.

Conclusion

AI in no-code applications makes advanced functions such as prediction, text analysis and document reading available to ordinary users. It saves time and effort, but the output of AI should always be verified by a human, and the privacy of business data should be kept in mind while using it.
